Surge protection for churches

White Paper

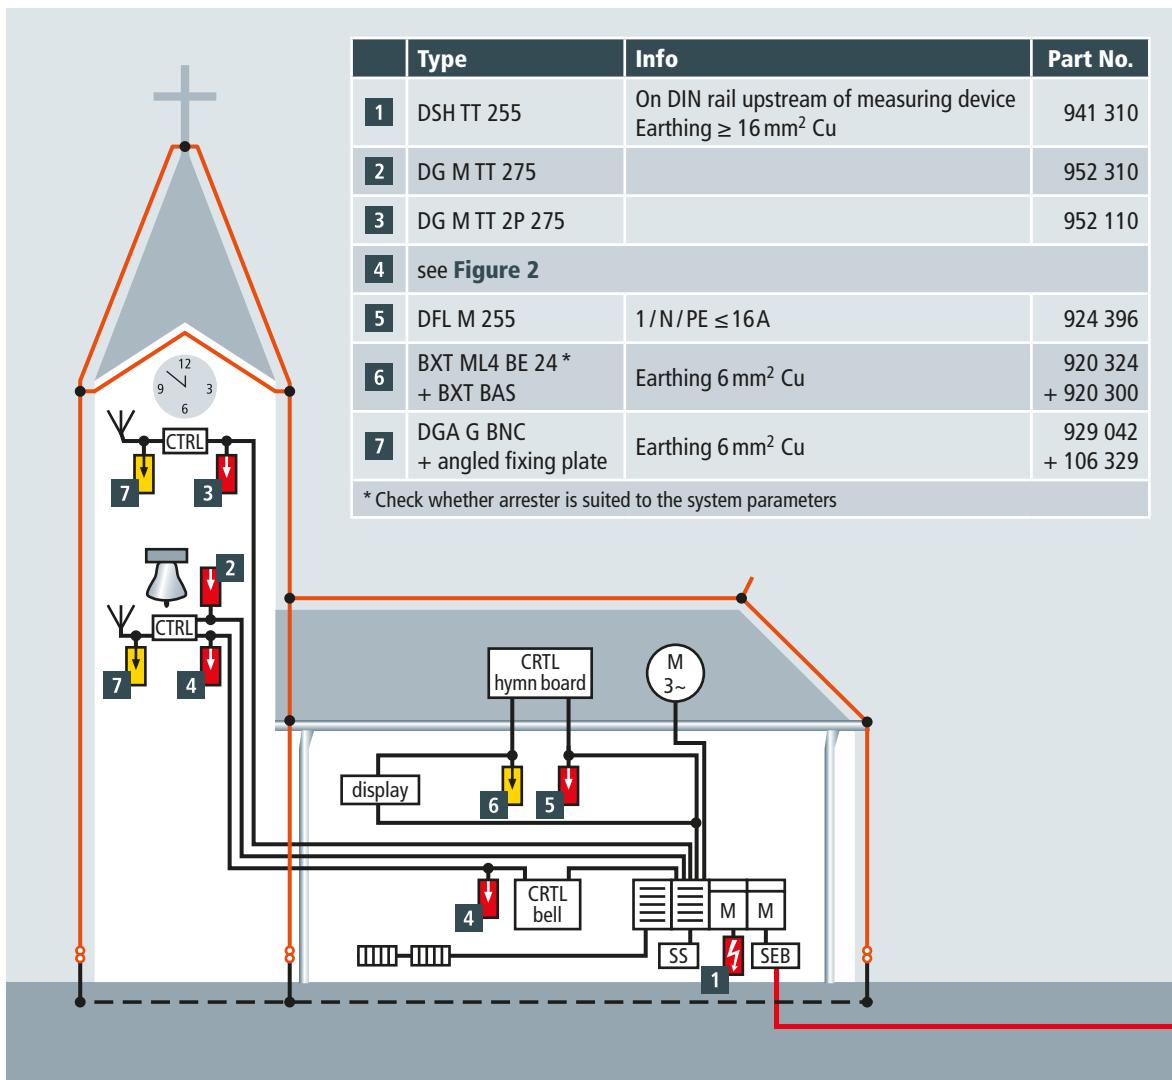

Figure 1 Principle of external and internal lightning protection for a church with steeple

Churches are buildings of high cultural value and places of public assembly. Therefore, they must be equipped with permanently effective lightning protection systems as described in chapter 18 of Supplement 2 of the German DIN EN 62305-3 lightning protection standard.

Figure 1 shows an example of the equipment frequently installed in churches. The circuit of the control line of the bell controller is illustrated in detail in **Figure 2**.

If the separation distance s is maintained between the down conductors/lightning current carrying parts and the cables installed in the steeple, flashover is not to be expected, however

electromagnetic coupling may occur. The following measures can be taken to minimise electromagnetic coupling:

- Short cable lengths
- No/little loop formation

If these measures are not feasible, surge protective devices must be installed.

Lightning equipotential bonding

A lightning protection system requires lightning equipotential bonding for metallic systems and all buried cables entering the building. In case of churches, equipotential bonding must

always be established for the low-voltage supply and other cables, if any (e.g. escape lighting).

Surge protection

Cables laid in the bell tower and nave are often very long or form loops. This mainly applies to the cables for the electric clock tower and the bell controller. Nowadays, both systems are time synchronised via the DCF 77 signal. Unless the hymn board is radio controlled, electromagnetic coupling has to be expected here, too.

In addition to the systems described above, the pipe heating system, electronic organ and sound system are also susceptible to electromagnetic coupling.
